

Part IV. Data Structures

Data structures are similar to containers since they can store one or multiple elements. However, they differ from containers because they don't support operations containers usually support. For example, it isn't possible, with the data structures introduced in this part, to access all elements in a single iteration.

- `Boost.Optional` makes it easy to mark optional return values. Objects created with `Boost.Optional` are either empty or contain a single element. With `Boost.Optional`, you don't need to use special values like a null pointer or -1 to indicate that a function might not have a return value.
- `Boost.Tuple` provides `boost::tuple`, a class that has been part of the standard library since C++11.
- `Boost.Any` and `Boost.Variant` let you create variables that can store values of different types. `Boost.Any` supports any arbitrary type, and `Boost.Variant` lets you pass the types that need to be supported as template parameters.
- `Boost.PropertyTree` provides a tree-like data structure. This library is typically used to help manage configuration data. The data can also be written to and loaded from a file in formats such as JSON.
- `Boost.DynamicBitset` provides a class that resembles `std::bitset` but is configured at runtime.
- `Boost.Tribool` provides a data type similar to `bool` that supports three states.
- `Boost.CompressedPair` defines the class `boost::compressed_pair`, which can replace `std::pair`. This class supports the so-called empty base class optimization.
